Group Reflection – Laboratory Equipment Booking System

Group members: [Write all group members' names]

In this assignment, we developed a Laboratory Equipment Booking System using a model-driven development approach.

We started by creating five UML diagrams and Architecture Decision Records (ADRs) to describe the system and its rules. We then used AI to explore the requirements, write a specification, create an implementation plan, and develop the application.

One challenge was understanding how the UML diagrams, specification, and JavaScript code were connected. We learned that defining clear requirements before implementation helps guide AI and reduces misunderstandings.

The group collaborated on discussions about the system design and decisions, while one member took the main responsibility for implementing the application with AI assistance.

We also learned how GitHub can be used to store project files, track changes, and publish a web application.
